12.13.6.16 Question: Bag I contains 3 red and 4 black balls and Bag II contains 4 red and 5 black balls. One ball is transferred from Bag I to Bag II and then a ball is drawn from Bag II. The ball so drawn is found to be red in colour. Find the probability that the transferred ball is black.

Answer: $(\frac{16}{31})$

Solution: By Bayes's Theorem we have, for any $i = 1, 2, 3, \dots, n$, where E_1, E_2, \dots, E_n be a set of events associated with a sample space S , where all the events E_1, E_2, \dots, E_n form a partition of S . For an event A associated with S ,

$$\Pr(E_i|A) = \frac{\Pr(E_i) \Pr(A|E_i)}{\sum_{k=1}^{k=n} \Pr(E_k) \Pr(A|E_k)}$$

Let R and B be the events that the ball transferred from Box-1 to Box-2 is Red and Black respectively.

$$\Pr(R) = \frac{\text{No. of Red balls}}{\text{Total Balls}} = \frac{3}{7} \quad (1)$$

$$\Pr(B) = \frac{\text{No. of Black balls}}{\text{Total Balls}} = \frac{4}{7} \quad (2)$$

Let's take the conditional probability for event E , which denotes the outcome of final ball drawn being Red.

When event R occurs, in Box-2 the count of red balls becomes 5 and black balls remains 5.

$$\Pr(E|R) = \frac{5}{10} \quad (3)$$

When event B occurs, in Box-2 the count of red balls remains 4 and black balls becomes 5.

$$\Pr(E|B) = \frac{4}{10} \quad (4)$$

By Bayes Theorem,

$$\Pr(E|B) = \frac{\Pr(E|B) \cdot \Pr(B)}{\Pr(E|B) \cdot \Pr(B) + \Pr(E|R) \cdot \Pr(R)} \quad (5)$$

where $\Pr(E|B)$ is the probability of final ball being red known that the transferred ball is Black, which is our desired final answer.

$$\Pr(E|B) = \frac{\frac{4}{10} \cdot \frac{4}{7}}{\frac{4}{10} \cdot \frac{4}{7} + \frac{5}{10} \cdot \frac{3}{7}} \quad (6)$$

$$\Pr(E|B) = \frac{16}{31} \quad (7)$$

The probability that the transferred ball is Black is $\frac{16}{31}$.
